OCEANOGRAPHY AND CLIMATE SYSTEMS

An Independent Research Project Exploring Ocean Circulation, Climate Regulation, Atmospheric Teleconnections, and the Role of Ocean Systems in Shaping Global Weather and Ecosystems

Prepared by: Sarp AKAR

Prospective Aerospace Engineering Student

Academic Mentor / Supervisor: Okan Kaan BİNZAT

Biology Teacher

ODTÜ Development Foundation Schools

Research Question: How do ocean currents and climate systems influence Earth's temperature balance, marine ecosystems, and global weather patterns? Furthermore, how does climate change affect these systems and their long-term stability?

Focus Areas: Oceanography, Climate Science, Data Analysis, Climate Systems, Scientific Research

Date: Sept 2026

Ankara, Türkiye

1. Ocean Currents and Global Thermal Balance (Oceanography)

1.1. Thermohaline Circulation: The Planet's Heat Conveyor Belt

While exploring National Geographic resources, I learned that oceans do far more than provide habitats for marine life. They are also among the most important regulators of Earth's climate. Oceans absorb large amounts of solar energy and redistribute that energy across the planet.

At the heart of this system is the Thermohaline Circulation, often referred to as the Global Ocean Conveyor Belt, which is driven by differences in water temperature ("thermo") and salinity ("haline"). As I examined this process more closely, I realized that the connection between physical ocean processes and marine ecosystems is much stronger than I had expected.

In polar regions, cold and highly saline water becomes denser and sinks toward the deep ocean. At the same time, warmer and less dense surface water moves toward the poles. This massive vertical and horizontal circulation transports oxygen to deep-sea ecosystems while bringing nutrient-rich waters containing nitrate and phosphate back toward the surface through a process known as upwelling.

These nutrients support the cellular metabolism of microalgae and phytoplankton, which form the foundation of marine primary productivity. In other words, the physical movement of the oceans directly supports life itself.

1.2. Wind-Driven Surface Currents and Ocean Gyres

Atmospheric wind systems, including the Trade Winds and Westerlies, together with the Coriolis Effect caused by Earth's rotation, generate enormous circular ocean current systems known as gyres.

While studying Khan Academy simulations, I realized that these gyres transport not only water but also vast amounts of thermal energy. This continuous redistribution of heat helps maintain global temperatures within a range suitable for life and supports the proper functioning of biological systems around the world.

2. The Gulf Stream and the Thermal Engine of Europe

2.1. The Dynamics of the Gulf Stream

The Gulf Stream is one of the most powerful and influential ocean currents on Earth. Originating in the Gulf of Mexico and extending toward Northwestern Europe, it transports between 30 and 80 million cubic meters of water every second, far exceeding the combined flow of the world's rivers.

By carrying tropical heat northward and releasing it into the atmosphere, the Gulf Stream plays a major role in moderating European climate and preventing much colder conditions across the continent.

2.2. Data Analysis: Climate Threats and Ocean Circulation Slowdown

While reviewing NOAA Ocean Exploration resources and studies of deep-sea sediment records, I realized that climate change may have a much greater influence on ocean circulation systems than I initially thought.

Melting polar ice releases enormous volumes of cold freshwater into the North Atlantic Ocean. Because freshwater reduces seawater density, it interferes with the sinking process that drives deep-water formation.

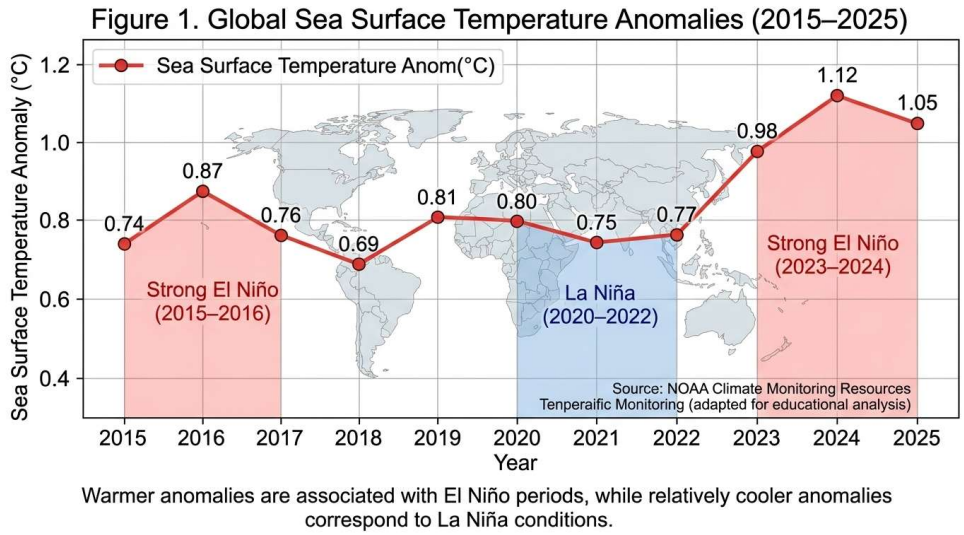

As a result, the Atlantic Meridional Overturning Circulation (AMOC), which includes the Gulf Stream, is currently considered weaker than at any point over the last 1,600 years.

This weakening could alter ocean temperatures, nutrient distribution, and ecosystem productivity, affecting marine species and regional climates. If the AMOC weakens further, significant climate consequences could occur across Europe and other regions of the world.

To better understand the relationship between ocean temperatures and climate systems, I examined sea surface temperature anomaly data published by NOAA.

The graph below shows annual sea surface temperature anomalies between 2015 and 2025.

Figure 1. Global Sea Surface Temperature Anomalies (2015–2025)

Warmer anomalies are associated with El Niño periods, while relatively cooler anomalies correspond to La Niña conditions.

Source: NOAA Climate Monitoring Database (2025)

The graph shows that sea surface temperature anomalies remained above the long-term average throughout the period. The highest anomalies occurred during 2023–2025, corresponding to a strong El Niño phase and exceptionally warm global ocean conditions. Comparatively lower anomalies were observed during the 2020–2022 La Niña period.

Although the temperature differences shown in the graph may appear relatively small, even minor changes in ocean temperatures can influence atmospheric circulation patterns, precipitation systems, marine productivity, and regional climate conditions.

The comparison between El Niño and La Niña periods demonstrates how variations in sea surface temperatures are closely linked to large-scale climate oscillations. This analysis helped me better understand how climate scientists use observational data to identify long-term environmental trends and monitor climate variability.

3. ENSO Dynamics: El Niño and La Niña

Sea surface temperatures and atmospheric pressure patterns across the Pacific Ocean drive one of the most influential climate oscillations on Earth: the El Niño-Southern Oscillation (ENSO).

3.1. El Niño: Warming Events and Atmospheric Teleconnections

Under normal conditions, trade winds push warm surface waters toward Asia while allowing cold, nutrient-rich waters to rise along the western coast of South America through upwelling.

During El Niño events, these trade winds weaken or even reverse.

- **Effects on Oceans and Marine Ecosystems:** Warm water migrates eastward, suppressing upwelling and reducing nutrient availability. As a result, phytoplankton productivity declines significantly, affecting the entire marine food web and potentially causing large reductions in fish and marine mammal populations.
- **Global Climate Effects:** Through atmospheric teleconnections, El Niño is commonly associated with increased rainfall in some regions of South America, while some areas of Australia, Indonesia, and Southern Africa may experience drier conditions. However, the exact impacts vary depending on regional climate systems and atmospheric conditions.

3.2. La Niña: Extreme Cooling Conditions

La Niña represents the opposite phase of ENSO.

- **Effects on Oceans and Marine Ecosystems:** Stronger-than-normal trade winds increase upwelling along the Pacific coast of South America. This process brings even more nutrient-rich water toward the surface and can significantly enhance marine productivity.
- **Global Climate Effects:** La Niña is frequently associated with cooler conditions in parts of North America, although regional impacts may vary from year to year.

4. Research Skills and Global Remote Sensing

Modern oceanographic research requires more than biological knowledge. It increasingly depends on the ability to interpret large datasets and use advanced technologies.

Scientists today rely on robotic Argo floats, satellite altimeters, and NOAA observation systems to collect real-time information about ocean temperature, salinity, currents, and climate trends.

While exploring these datasets, I realized that modern science extends far beyond traditional laboratories. Data systems, computational tools, and satellite technologies have become essential components of scientific discovery.

This experience helped me better understand the relationship between biology, environmental science, and data analysis.

5. Future Plans and Career Goals

This project strengthened my interest in scientific modeling, data analysis, and understanding how large systems work.

While studying ocean circulation and climate systems, I became increasingly interested in how scientists and engineers use data and models to explain complex real-world processes.

Although my academic interests have gradually expanded toward Aerospace Engineering, I still enjoy exploring how different systems interact and influence one another. Whether studying climate, engineering, or technology, I am fascinated by the challenge of understanding how complex systems work. In the future, I hope to continue developing my skills in science, engineering, programming, and data analysis while exploring new ways to solve real-world problems through technology and innovation.

6. Report Conclusion

This project showed me how important oceans are in regulating Earth's climate and supporting marine life.

Through ocean circulation, climate systems, and large-scale environmental processes, I learned how different parts of our planet are connected and influence one another.

The project also helped me better understand how scientific observations, climate data, and research are used to explain complex environmental systems.

Through thermohaline circulation and wind-driven gyres, the oceans function as a global thermal engine that redistributes heat energy and supports the biogeochemical cycling of nutrients essential for marine productivity.

This research demonstrates that disruptions in large-scale ocean circulation systems, including AMOC weakening and ENSO variability, can affect climate patterns, ecosystem stability, and marine productivity on a global scale.

One of the most surprising things I learned during this project was that relatively small changes in ocean temperatures can influence climate systems across entire continents. Before conducting this research, I did not realize how closely connected ocean circulation, atmospheric processes, and weather patterns are. Learning about these connections changed the way I think about Earth's climate as an interconnected system rather than a collection of separate events.

Ultimately, understanding these systems requires an interdisciplinary perspective that combines physical oceanography, climate science, big data analysis, and environmental research.

7. Personal Reflection

Through this project, I learned that oceans do much more than provide habitats for marine life.

Before starting this research, I mostly thought of oceans as places where marine ecosystems exist. However, as I explored ocean circulation and climate systems, I realized that oceans play a major role in regulating global temperatures, moving nutrients around the planet, and influencing weather patterns.

One of the things that impressed me most was seeing how connected everything is. Concepts like thermohaline circulation, AMOC, El Niño, and La Niña showed me that even small changes in one part of a system can lead to much larger effects elsewhere.

What I enjoyed most about this project was learning how scientists use observations, data, and models to better understand these complex systems. It helped me develop a stronger interest in data analysis, systems thinking, and scientific problem-solving.

Although my interests have recently started shifting toward Aerospace Engineering, projects like this continue to shape the way I think about science, technology, and complex systems.

As someone who is interested in Aerospace Engineering, I also found it fascinating that many of the technologies used to study the oceans, including satellites, remote sensing systems, and data modeling techniques, are closely related to tools used in aviation and space research.

Most importantly, it reminded me that understanding how systems behave is often just as interesting as understanding the individual parts that make them work.

8. Skills Developed

- Data Analysis
- Scientific Research
- Critical Thinking
- Climate Science
- Oceanography
- Environmental Science
- Problem Solving
